Colin McCarthy @US\_Stormwatch · Aug 30

Hard to comprehend the scale of the flood disaster in Pakistan, the 5th most populated nation in the world.

Nearly 1400 dead, 1 million houses damaged or destroyed, and 50,000,000 people displaced.

1/3 of the country is underwater.

# Research questions

- to use ML classifier to estimate probabilities of debris-flow vs flood dominated system
- to identify the parameters, that matter for the classification
- to see if adding climatic features affects the classification
- to find out if there are any regional differences
- to make projections based on climate scenarios

For thousands of data points and moderate dimensionality (99% of cases), gradient-boosted trees provide the necessary regression model  
[scikit-learn.org/stable/modules...](https://scikit-learn.org/stable/modules...)

They are robust to data distribution and support missing values (even outside MAR<sup>\*</sup> settings  
[arxiv.org/abs/1902.06931](https://arxiv.org/abs/1902.06931))

\* MAR = Missing At Random

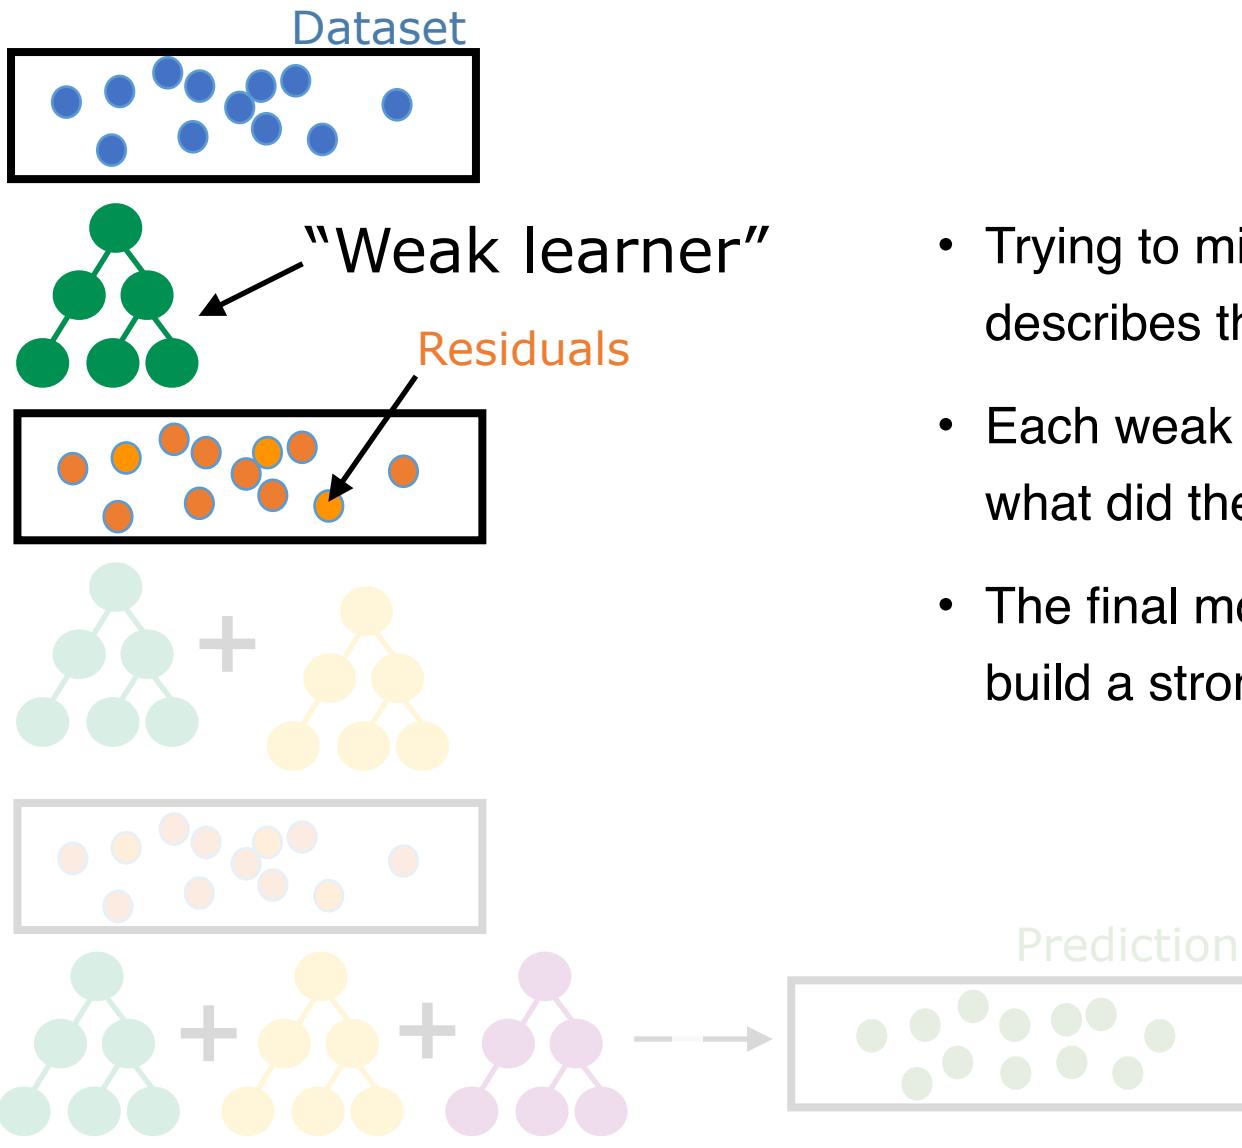

# Gradient boosted decision trees

- Trying to minimize the “loss function” (function, that describes the error) on every iteration
- Each weak learner (i.e. tree/iteration) is trying to learn what did the previous one did “wrong” and do better
- The final model is the “combination” of all weak trees to build a strong classifier

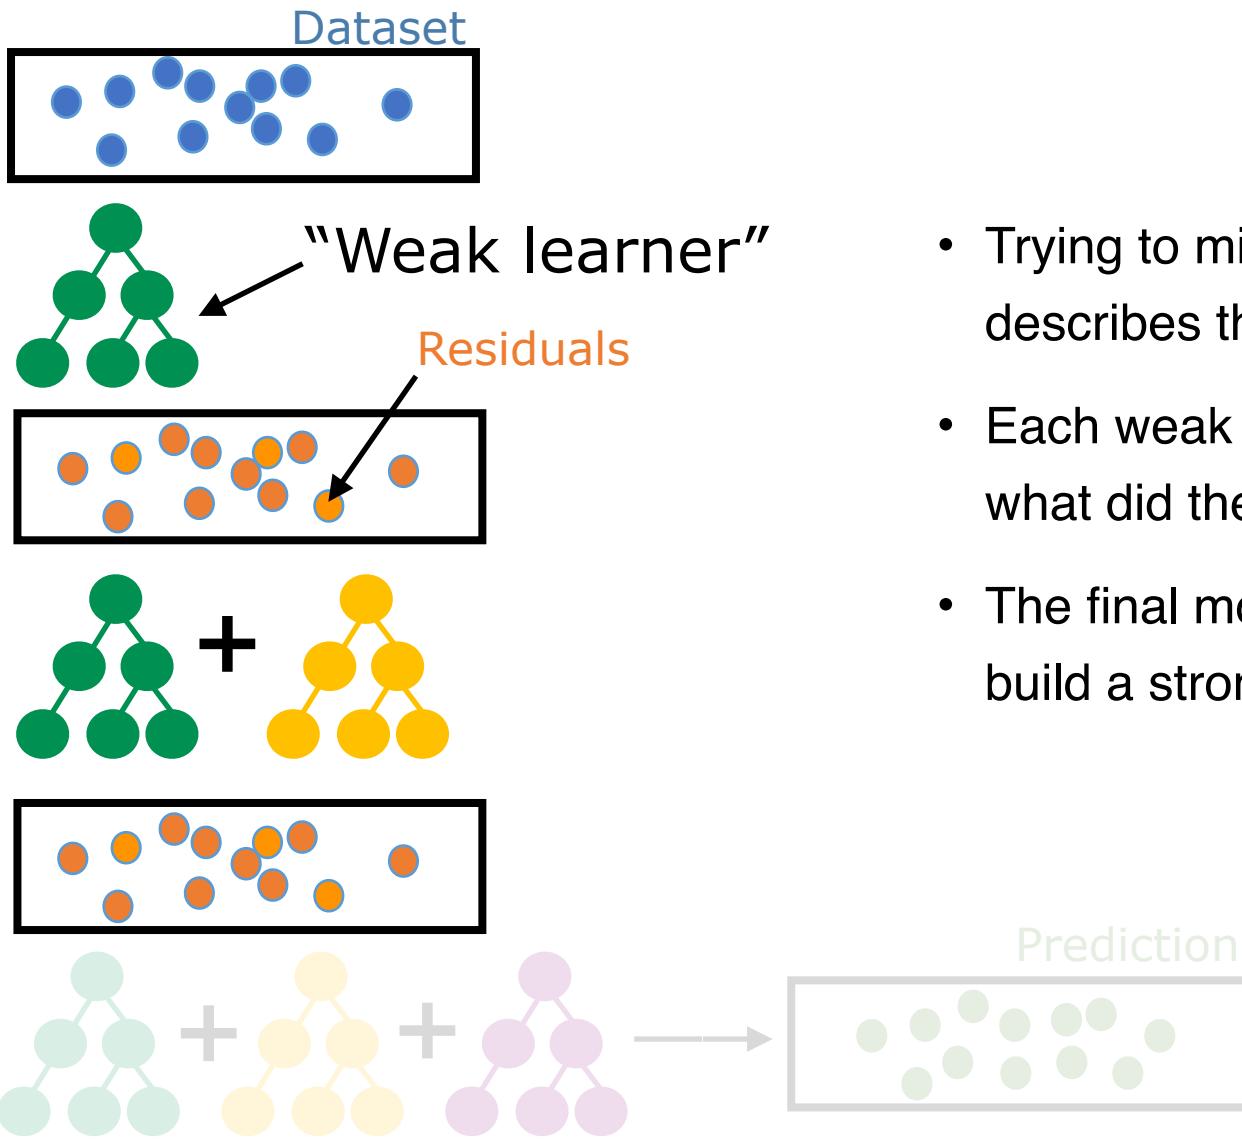

# Gradient boosted decision trees

- Each weak learner (i.e. tree/iteration) is trying to learn what did the previous one did “wrong” and do better
- The final model is the “combination” of all weak trees to build a strong classifier

# Implementation: Catboost

- Does a good job as an “out of the box” tool
- Supports **categorical** features (predictors) as an input

# Building the model: how good is it?

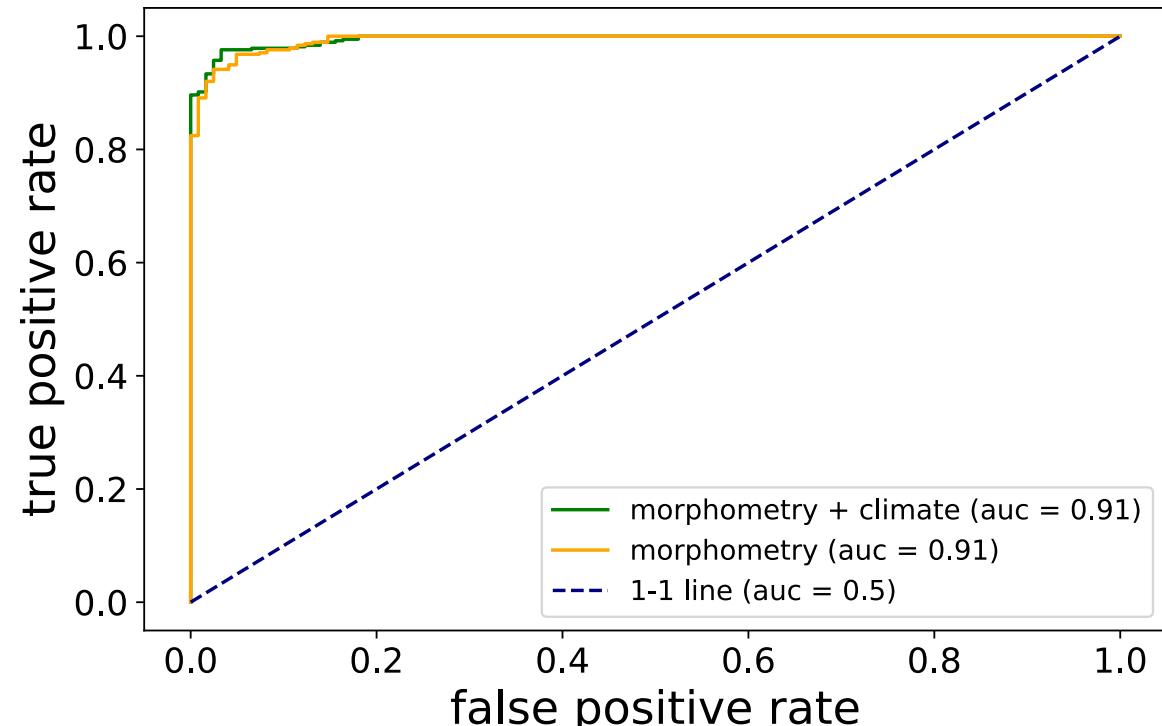

## Morphometric

- Accuracy : 91 %  
(fraction of correct predictions)
- Confusion matrix: [145., 28.]  
[ 17., 522.]

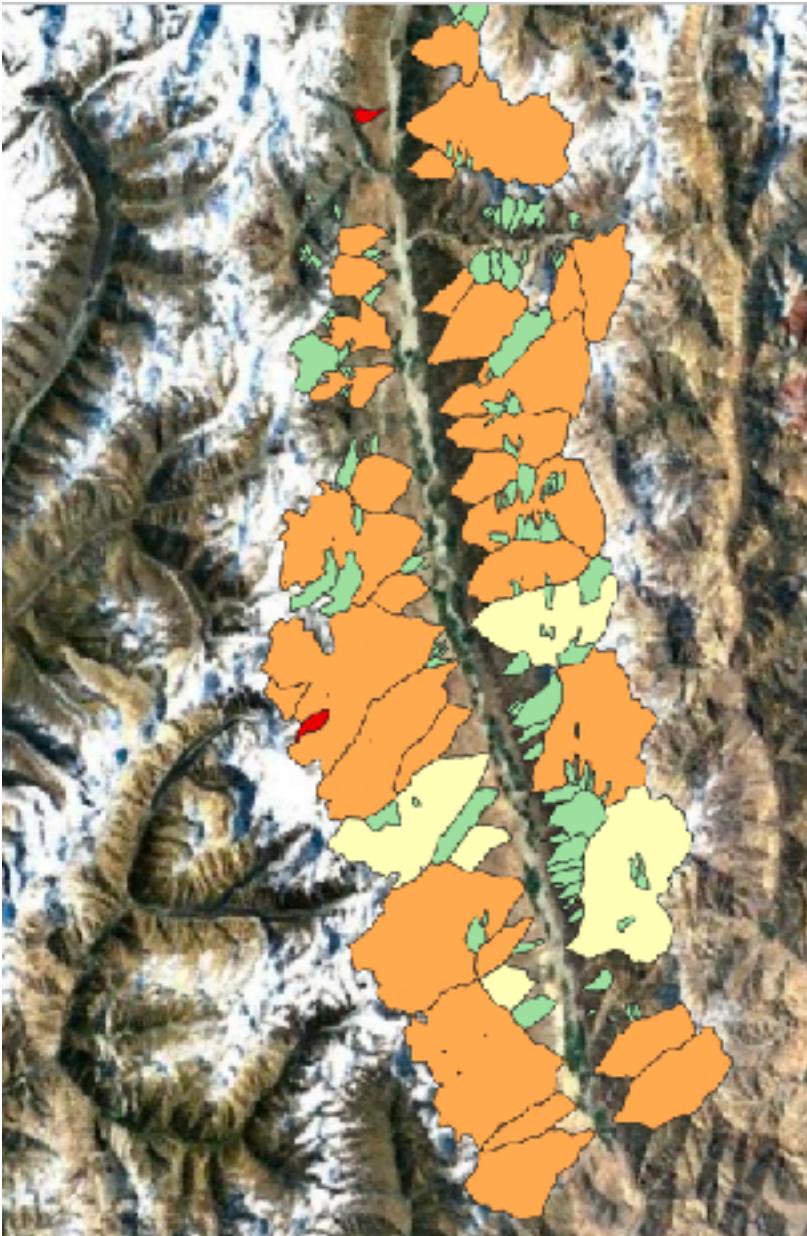

## Morphometric + climate

- Accuracy: 92 %
- Confusion matrix: [148., 25.]  
[ 14., 525.]

TP	FN
FP	TN

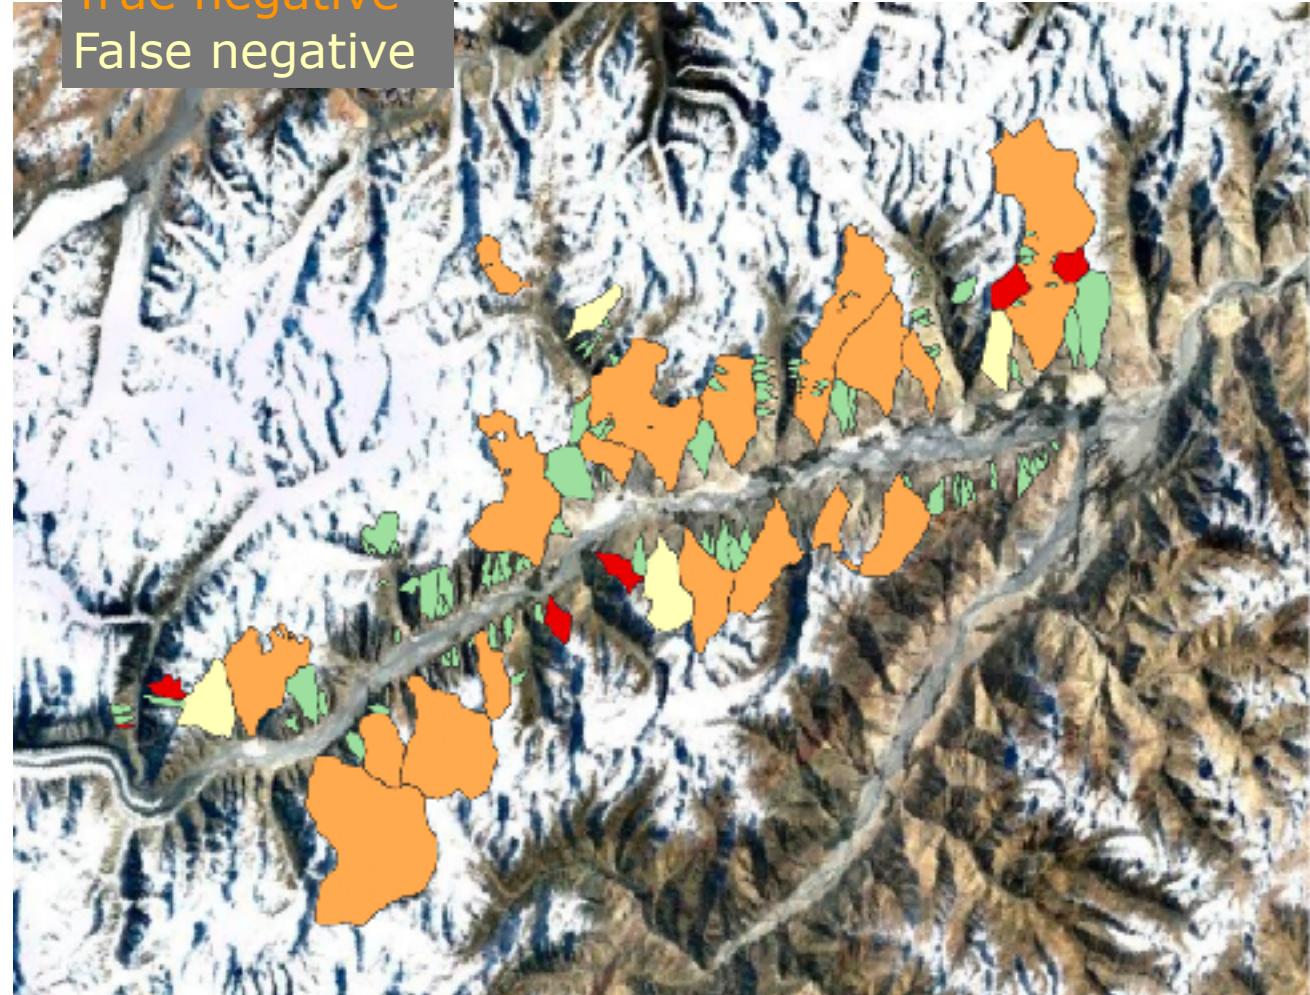

- auc = area under curve
- only “tuned” parameter: number of trees (iterations)
- debris flow (1): 539, flood (0): 173
- accuracy, when guessing randomly: 75.7 %

# Why does Catboost model make this predictions?

Morphometric

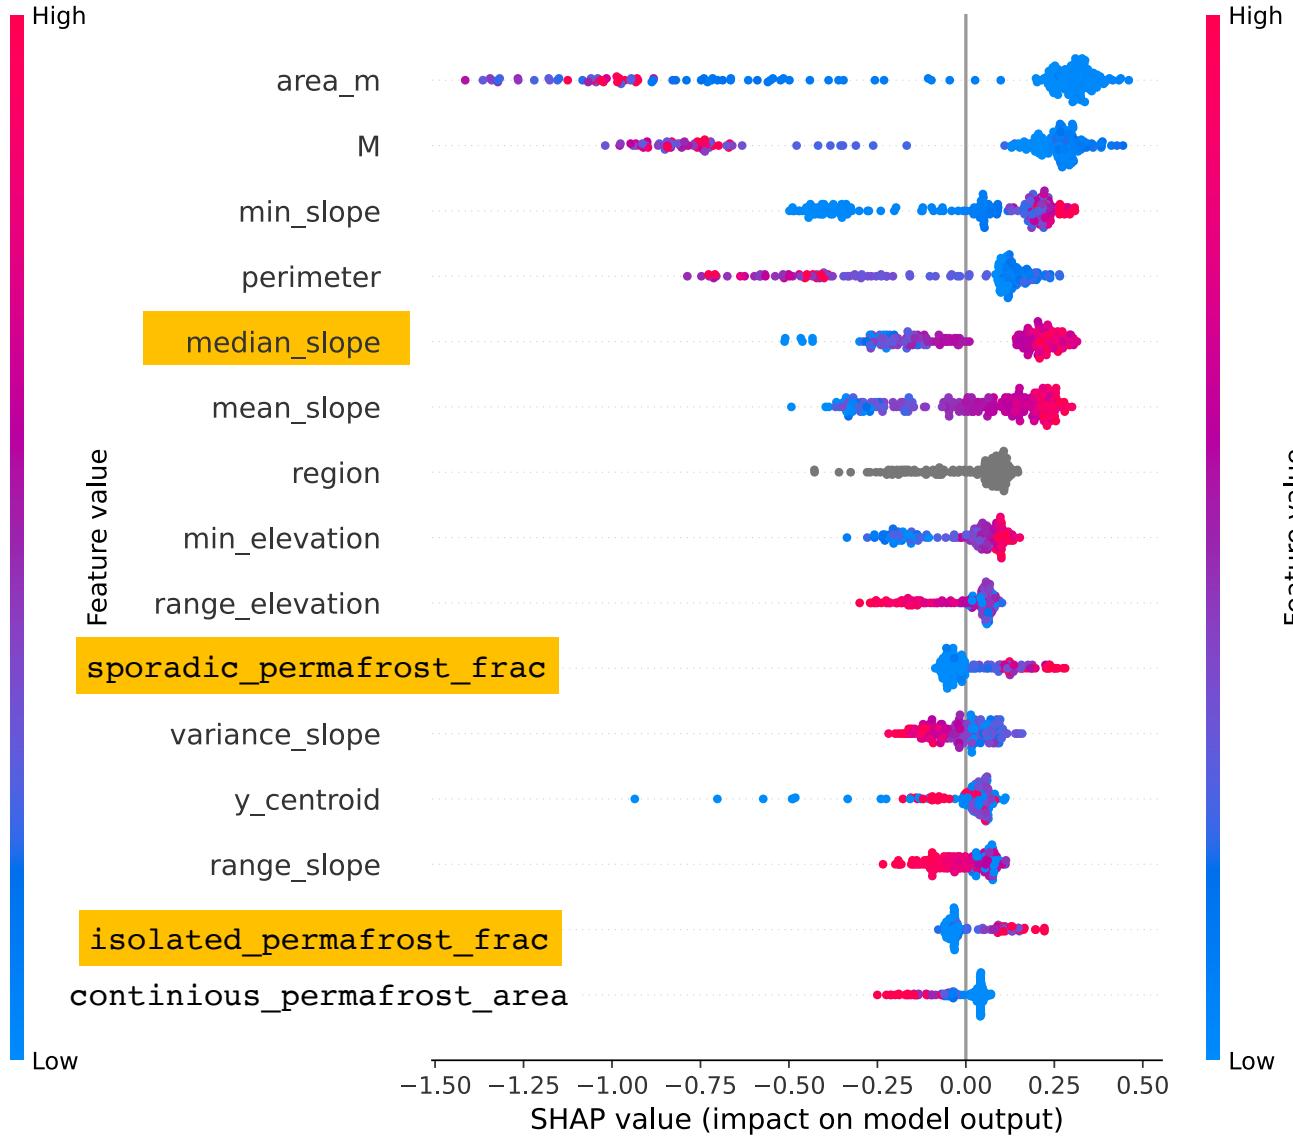

Morphometric + climate

## What should we do to the catchment for it to “switch”:

all things being equal, how can we make a “flood” catchment produce “debris flow”

*average probability of a DF (1)  
for scenario, where all catchment  
have the same area (x-axis)*

# Conclusions

- We can build a machine learning classifier for distinguishing debris-flow dominated systems from flood dominated ones
- Climate data adds a lot of information to the model, but (all other things being equal) does not improve model performance

# Outlook

- Extend the dataset for “creating” the model by covering more diverse regions
- Add vegetation cover to the feature list
- Apply the model to the “new” areas (i.e. catchments without alluvial fan)
- To see the effect of the climate change - use RCP scenarios as a climate information
